

## Editorial

Time is flying and we're already entering our second year of CONCERT.

In year 1, we implemented two major dissemination tools: the AIR2 Bulletin and the AIR2D2 database, both of which will reach cruising speed during AWP2.

Our focus will now shift to Quality Management. Two brainstorming days for WP6 "Access to Infrastructures" will be organised in Brussels on 11-12 July. Starting with a Workshop on subtask WP6.2.2, our aim will be to define suitable harmonisation exercises and protocols that can be developed for CONCERT infrastructures. Day 2 will be dedicated to in-depth discussion of each WP6 task and subtask. The programme is available [here](#).

To contribute to any point, please contact us with your suggestions, feedback or questions. - **Dr Laure Sabatier**

## The floor to...

The application of ionising radiation should do more good than harm. All those who work in radiation protection research have an obligation to fulfil this public expectation. This is challenging, however, because the health hazards from ionising radiation depend on the dose, and because there exist various natural and artificial sources of ionising radiation.

For a quantitative risk-benefit analysis, radiation doses must be determined as reliably as possible. One of the missions of EURADOS is to harmonise dosimetric practices in Europe to ensure that doses are determined with similar and acceptable accuracy for a wide range of applications, radiation qualities, energies and conditions. Infrastructures such as irradiation facilities are indispensable to this process.

EURADOS organises intercomparisons where instruments are irradiated under the same conditions at different reference facilities. Instruments include those used for occupational, medical or environmental dosimetry, or for retrospective dosimetry relevant to emergency dosimetry networks such as RENE. The participants are asked to report the doses obtained with their instruments. Statistical analysis demonstrates the consistency of the measured doses and identifies any outliers. Overall results are discussed and recommendations to improve

**"Doses must be accurately determined, and infrastructure plays a central role in this effort"**

dosimetric practices are provided. This procedure, also used for the harmonisation of computational dosimetry techniques using computing facilities, has led to significant improvements in the consistency of dose quantification in Europe.

Furthermore, instrumentation for the detection of ionising radiation must be continuously developed as technology advances and new ap-

lications of ionising radiation evolve. For example, there is an increasing need to develop methods for high-energy secondary neutron detection in particle cancer therapy. Quantification of doses in pulsed radiation fields also poses major problems when electronic dosimeters are used. These and other technical developments can only be pursued if proper irradiation facilities are available.

The application of ionising radiation should do more good than harm. To guarantee this, doses must be accurately determined, and infrastructure plays a central role in this effort.

**Prof. Dr. Werner Rühm –  
Helmholtz Zentrum München  
EURADOS Chairperson**

# Exposure platforms

## Mixed alpha and X-ray exposure facility Simultaneous exposure of cells to high and low LET radiation

People are often simultaneously exposed to a mixed field of low and high linear energy transfer (LET) radiation. The most common scenario occurs in areas with high natural background radiation, where both the levels of gamma radiation and indoor radon are elevated. Another situation occurs during aeroplane and space flights where cosmic high LET radi-

tion interacts with shielding material to produce gamma radiation. Finally, radiotherapy patients treated with intensity-modulated radiation therapy, fast neutron therapy and boron neutron capture therapy are exposed to mixed beams of neutrons and photons.

An important question related to the health effects of exposure to mixed beams is whether the risk can be calculated by simply adding the effects of the low and high LET dose components or whether the different radiations act in a synergistic manner. The available experimental data do not allow a definite conclusion to be drawn. Indeed, both additivity and synergism have been reported. The reason for this discrepancy is not understood but one factor could be that cells are exposed sequentially, rather than simultaneously, to the two types of radiation. Simultaneous irradiation is the desirable scenario but requires a dedicated irradiation facility. At Stockholm University, a facility has been constructed where cells can be simultaneously exposed to <sup>241</sup>Am alpha particles and X-rays at 37 °C.

The facility consists of an alpha irradiator, custom-constructed in the Institute of Nuclear Chemistry and Technology, Warsaw, Poland, an X-ray tube (YXLON SMART 200, Yxlon International, Hamburg, Germany)

and a 164 l cell incubator. The alpha irradiator is positioned inside and the X-ray tube under the incubator. The whole setup is placed in a lead container so that it can be safely operated in a laboratory room.

The source of alpha radiation is <sup>241</sup>Am (Eckert and Ziegler, Berlin, Germany) with a total activity of 50 MBq. The source is attached to a steel disc that in turn is glued to a circular turn-table, with the active side (ca 15 cm in diameter) facing downwards. Below the source is an aluminium shelf on which cells on polyamide discs can be positioned for exposure and covered by a Mylar foil. The shelf can be moved vertically by a remote-controlled step-engine. The X-ray tube is operated at 190 kV, 4.0 mA without any additional filtering.

The facility works as intended, allowing exposure of cells to alpha particles, X-rays and a combination of both in a temperature-controlled environment. It allows to further characterise the response of cells, both adherent and in suspension, to mixed beams of high and low LET, thus providing the opportunity to generate much needed data on the effect of mixed beams of ionizing radiation.

## French longitudinal study of children (Elfe) 18,000 children followed from birth to adulthood

The conditions in which children live and grow are changing fast. Research is therefore needed to find out more about how children's environment in their early years affects their development, their health and even their socialisation. A cohort follow-up study is the best means of closely monitoring children's trajectories. This involves recruiting a large sample of children and tracking them throughout their development.

It was for precisely this reason that Elfe was set up, taking into account questions submitted by 15 themed groups representing more than 150 researchers, as well as concerns expressed by various public bodies. Launched in metropolitan France in April 2011, this resolutely

and development. Regarding physical agents, for example, the radon study undertaken by a team from the French Institute for Public Health Surveillance (InVS) seeks to identify variations in childhood exposure to radon in the home. A further aim is to assess the public health risks for the dose levels that are observed, and revisit current hypotheses on the dose-response relationship. The medical radiation study, meanwhile, led by researchers from

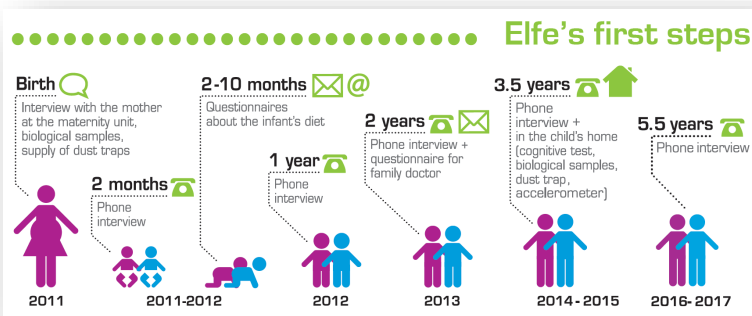

Source: Guenet/Inserm

Marie-Aline Charles

the French Institute for Radiological Protection and Nuclear Safety (IRSN), is intended to provide a detailed and exhaustive picture of children's exposure to diagnostic medical imaging with or without ionizing radiation (IR). It will then be possible to establish dosimetric estimates of IR exposure, based on standardised measurements

or literature findings. A second objective will be to join international consortiums collecting the same sort of data, in order to assess the risk of cancer and other pathologies potentially associated with this exposure.

Since 2013, Elfe data have been available to researchers actively involved in the study - mainly in the design of its questionnaires, and a year ago, access was extended to the whole of the scientific community, under certain conditions.

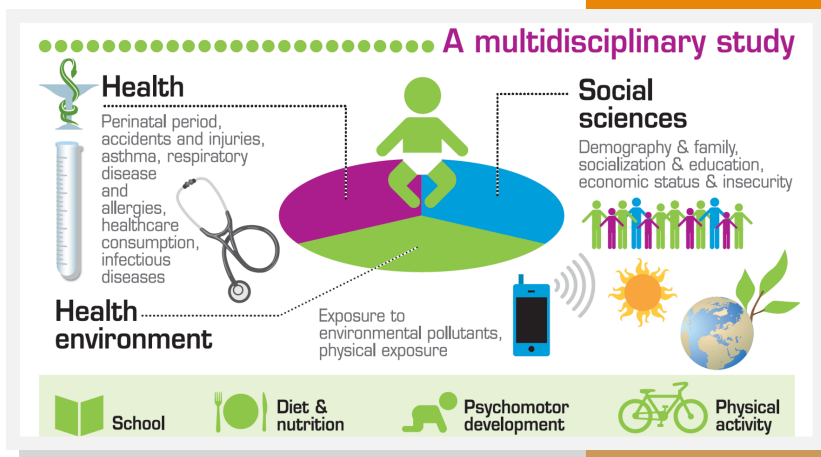

multidisciplinary study recruited more than 18,000 children born that year.

The bulk of the data has so far been collected via surveys of the children's parents (telephone interviews at the 2-month, 1-year, 2-year and 3.5-year milestones or postal/Internet questionnaires). The children were directly studied for the first time when they reached the age of 3.5 years, on the occasion of a home visit during the 2014-2015 wave.

Alongside the cohort, we have set up a biobank containing samples from a subgroup of Elfe families. These were collected in the maternity units where the children were born (mother's urine, venous blood, hair and breast milk, cord blood, newborn's meconium/stool), and again during the survey at 3.5 years (child's hair, urine and stool).

The research carried out by the Elfe teams can be placed under three main headings: health, social sciences and the environment. In the latter, the emphasis is on measuring exposure to various chemical substances or physical agents and studying their impact on children's health

## ERICA Tool

### The ERICA Tool supports adept environmental risk assessment

A key component of the ERICA Integrated Approach was the quantification of environmental risk involving, as an initial step, the combination of data on environmental transfer and dosimetry to provide a measure of wildlife exposure. These values, in the form of dose rates or corresponding activity concentrations for screening purposes, could then be compared with benchmarks, derived from exposure levels at which detrimental effects are known to

key procedural element of Tier 2 involves the application of Uncertainty Factors, UFs. Such factors reflect knowledge concerning probability distribution functions and provide a way of incorporating conservatism into the assessment by allowing the consideration of high percentile values in underlying parameters. Tier 3 allows a fully probabilistic analysis to be undertaken.

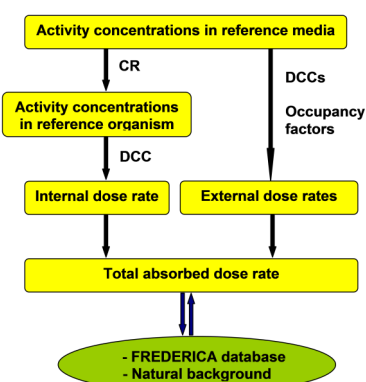

Photo: Justin Brown/NRPA

Justin Brown

The ERICA Tool has been further evaluated in numerous studies and has been widely applied by the scientific community. Examples include: consideration of potential environmental impacts from deep geological disposal facilities in various European countries; scoping analyses in line with newly introduced environmental regulations; in quantifying environmental impacts from operating and planned nuclear power stations and assessments of the impact of near-surface radioactive waste repositories in Europe and Australia.

Training in the use of the Tool has been relatively comprehensive (see: <https://wiki.ceb.ac.uk/x/dIPJBg>) with a bespoke 'Questions & Answers' webpage having been developed (see: <https://wiki.ceb.ac.uk/x/r48ZBw>). The software is freely available for download (<http://www.ERICA-tool.com> and <http://www.ERICA-tool.eu/>) with the newest version of the software described in Brown et al. (2016).

Components within the assessment part of the ERICA Tool

occur, for the estimation of risk. In view of the large data sets underpinning the assessment approach and the potential to introduce errors when performing numerous calculations by hand, a supporting computer-based tool, the ERICA Tool, was developed as described in Brown et al. (2008). The Tool gives the option to cover a comprehensive list of radioisotopes and organism types, and has particular emphasis on the assessment of planned routine discharges of radionuclides and existing exposure situations.

The ERICA Tool adopts a tiered structure. There are two generic screening tiers and a third site-specific tier. The first Tier is very simple, based around Environmental Media Concentration Limits, EMCLs, defined as the activity concentration of a given radionuclide in media (soil, sediment water) that will result in a dose-rate to the most exposed reference organism equal to the screening dose-rate. This Tier requires minimal input from the assessor. The second Tier, although still a screening tier, is used to calculate dose rates explicitly and requires more detailed input from the assessor allowing for scrutiny and editing of default parameters in the process. A
